## KEYNESIAN THEORY AND POLICY AT A GLANCE DERIVATION OF THE INVESTMENT MULTIPLIER

The notion of an investment multiplier is most relevant when (1) the economy is functioning somewhere below its full-employment level and (2) market forces, which normally impinge on prices, wages and the interest rate, are (for some reason) not working. In these circumstances, a (Keynesian) macroeconomic equilibrium (one involving a substantial amount of economywide unemployment) is achieved through changes in the levels of spending and income.

When the level of investment increases by some amount, $\Delta \mathrm{I}$, the equilibrium level of income will increase by some multiple amount, $\Delta \mathrm{Y}$. The ratio of $\Delta \mathrm{Y}$ to $\Delta \mathrm{I}$ is called the investment multiplier. It can be derived, as follows, from the equilibrium condition $(Y=C+I+G)$ together with the consumption equation $(C=a+b Y)$.

1. $\mathrm{Y}=\mathrm{C}+\mathrm{I}+\mathrm{G}$ where $\mathrm{C}=\mathrm{a}+\mathrm{bY}$
2. $Y=a+b Y+I+G$
3. $\mathrm{Y}+\Delta \mathrm{Y}=\mathrm{a}+\mathrm{b}(\mathrm{Y}+\Delta \mathrm{Y})+\mathrm{I}+\Delta \mathrm{I}+\mathrm{G}$
4. $\mathrm{Y}+\Delta_{-} \mathrm{Y}=\mathrm{a}+\mathrm{bY}+\mathrm{b} \Delta \mathrm{Y}+\mathrm{I}+\Delta \mathrm{I}+\mathrm{G}$
5. $\mathrm{Y}=\mathrm{a}+\mathrm{bY}+\mathrm{I}+\mathrm{G}$
6. $\Delta \mathrm{Y}=\quad$ b $\Delta \mathrm{Y}+\Delta \mathrm{I}$
7. $\Delta \mathrm{Y}-\mathrm{b} \Delta \mathrm{Y}=\Delta \mathrm{I}$
8. $(1-b) \Delta Y=\Delta I$
9. $\Delta \mathrm{Y}=\frac{\Delta \mathrm{I}}{(1-\mathrm{b})}$
or 10. $\frac{\Delta \mathrm{Y}}{\Delta \mathrm{I}}=\frac{1}{(1-\mathrm{b})}$
The 10 -step derivation above consists of the following sequence of manipulations:
10. Write the equilibrium condition letting it describe the initial equilibrium.
11. Replace C in this equation with its algebraic equivalent, $\mathrm{a}+\mathrm{bY}$.
12. Rewrite equation 3 substituting $Y+\Delta Y$ for $Y$ and $I+\Delta I$ for $I$. This equation describes the new equilibrium, once the economy has adjusted to the increase in the level of investment.
13. Remove the parentheses in step 4, algebraically.
14. Rewrite equation 3 aligning the corresponding terms.
15. Subtract equation 5 from equation 4 .
16. Transpose $\mathrm{b} \Delta \mathrm{Y}$ to the left side of the equation.
17. Factor out the $\Delta Y$.
18. Divide both sides of the equation by $(1-b)$. This equation tells us that if we know that the level of investment has been increased by $\Delta \mathrm{I}$, we can multiply by $1 /(1-b)$ to determine the corresponding increase $(\Delta \mathrm{Y})$ in the level of income.
19. Alternatively, divide both sides of this equation by $\Delta \mathrm{I}$ to get the defining statement of the investment multiplier. Note that the investment multiplier is simply the reciprocal of the marginal propensity to save.
